(Z. Naturforsch. 32a, 152–155 [1977]; received January 6, 1977)

Results of a microwave investigation of the molecules 2-Cyanothiophene and 2-Cyanofurane are reported. The microwave spectrum of 2-Cyanothiophene was examined in the frequency range of \(13–40\) GHz mainly to get a more accurate rotational constant \(\bar{A}\) from the assignment of \(\mu_J\)-transitions. From the resolved hyperfine structure due to nuclear quadrupole coupling of the \(^{14}\)N-nucleus the quadrupole coupling constant \(\chi = \chi_{bb} + \chi_{cc}\) was determined for 2-Cyanothiophene. No information for \(\chi_{aa}\) was available from the measured transitions.

From Stark effect studies the dipole moments were determined for both molecules. The nuclear quadrupole coupling as a perturbation of the second order Stark effect was included in the Stark effect analysis.

Since the two molecules 2-Cyanothiophene and 2-Cyanofurane differ only by the isoelectronic ring atoms sulfur and oxygen they were investigated in parallel. In a preceding paper \(^1\) we reported the rotational constants and the nuclear quadrupole coupling constants of 2-Cyanofurane. When our analysis of the spectrum of 2-Cyanothiophene was finished we noticed a publication of Avirah et al. \(^2\) on the microwave spectrum of this compound. As our data are more complete and partly different they will be included in this publication.

### Experimental

The spectra of both compounds were recorded in the region between 10 and 40 GHz with conventional microwave spectrometers using 30 and 100 kHz Stark modulation \(^3\), \(^4\). For the assignment of the rotational spectrum of 2-Cyanothiophene radio frequency microwave double resonance (RFMWDR) \(^5\) was of great help. The compounds were purchased from EGA-Chemie and used after distillation.

### 2-Cyanothiophene

The rotational spectrum exhibits rather strong \(\mu_{J}\)- and weak \(\mu_{J}\)-transitions. With the combined use of Stark-modulated and RFMWDR-spectroscopy, the initial assignment of the \(\mu_{J}\)- and \(\mu_{J}\)-transitions was possible. The measured transitions are given in Table 1.

* Reported by Avirah et al. 2.

Table 1. Those given by Avirah et al. 2 are marked with an asterisk. A search for $\mu_J \pi$-transitions proved to be rather tedious because of the low intensity and overlapping of lines.

The spectrum was analysed by the model of the centrifugal distorted rotor according to Watson 6. Table 2 gives the rotational and centrifugal distortion constants and their correlation coefficients. For comparison with the results of Avirah et al. 2 lines with $J \leq 9$ were used to fit the rotational constants of the rigid rotor. Our values differ by inclusion of $\mu_J \pi$-transitions, which determine the rotational constant $A$ more reliably.

From the resolved quadrupole hyperfine structure due to the $^{14}$N-nucleus given in Table 3, the quadrupole coupling constant $\chi_+ = \chi_{bb} + \chi_{cc}$ was determined to $4.04 \pm 0.16$ MHz. An extended search for lines sensitive to $\chi_- = \chi_{bb} - \chi_{cc}$ was unsuccessful.

A comparison of $\chi_+$ of 2-Cyanothiophene with that of 2-Cyanofuran shows that both values are equal within the error limits. As further the orientation of the principal axis system of 2-Cyanothiophene (Fig. 1) is similar to that of 2-Cyanofuran (Fig. 1 1) the $\chi_- = 0.96$ of 2-Cyanofuran may be taken as a rough approximation also for 2-Cyanothiophene.

Stark-energy matrix of a $J, \tau$ level after application of second order Stark effect perturbation with added elements of $\mathcal{H}_Q$

$$E_{\text{St, } M_J} = J + c$$

$a, b, c, x, y$ are the matrix elements of $\mathcal{H}_Q$ with

$$a = \frac{1}{2} \left[ (J+1) - 3 \right] \frac{1}{2} \left[ (\tau+1) - 3 \right] \cdot C(J, \tau, I),$$

$$b = \frac{1}{2} \left[ J(J+1) \right] \frac{1}{2} \left[ (\tau+1) \right] \cdot C(J, \tau, I),$$

$$c = \frac{1}{2} \left[ (J(J+1) - 3 \left[ J - 3 \right] \cdot C(J, \tau, I),$$

$$C(J, \tau, I) = \left( \sum_{\sigma} \langle J, I \left| J_\sigma \right| J \rangle \langle J \right| \langle \sigma \left| I \rangle \right) / (2J+1) \right).$$

**Dipole Moments**

The dipole moment components $\mu_a$ and $\mu_b$ were determined from second order Stark effect lines. Those of 2-Cyanothiophene were calculated by diagonalisation of the Stark energy matrix as the used transitions have very sensitive Stark satellites. Both dipole moment components were fitted together to the Stark effect satellites $|M_J| = 0, 1, 2, 3, 4$ of the transition $5_{32} - 6_{23}$ at $19340.46$ MHz and to the satellites $|M_J| = 1, 2$ of the transition $4_{33} - 5_{24}$ at $15783.05$ MHz. The electric field strength used for the measurement of the dipole moment was determined by calibration with OCS $J = 0 - 1$. The calculated dipole moments are listed in Table 4. The quoted errors include both the single standard error of the fit and the calibration uncertainty. The discrepancy between the values of Avirah et al.\textsuperscript{2} and ours for 2-Cyanothiophene may indicate that the quoted error limits have to be considered with caution.

The dipole moment components of 2-Cyanothiophene were determined by a calculation, which applies first the second order Stark effect perturbation and second the perturbation by the $^{14}$N-quadrupole coupling. If the strong field case is assumed with an effective decoupling of overall rotation and nuclear spin, all off-diagonal matrix elements with respect to $M_J$ and $M_I$, the projection quantum numbers of the overall rotation and nuclear spin respectively, for a given rotational level denoted by $J, \tau, M_J$ and the nuclear spin $I$ are small compared to the diagonal matrix elements by the second order Stark effect perturbation and the quadrupole coupling operator $\mathcal{H}_Q$ (compare Ref.\textsuperscript{8}). However, it is not possible to apply second order perturbation theory again because the $(M_J, M_I)$-sublevels $(-1, +1)$ and $(+1, -1)$ are degenerate and connected by an off-diagonal element of $\mathcal{H}_Q$. The energy matrix for a given rotational level has the form indicated in Figure 2. Only the matrix elements involving the degenerate sublevels and $M_J, M_I = 0, 0$ are given completely. The degeneracy is removed by the application of the orthogonal transformation of Fig. 3 to the energy matrix of Figure 2. The transforma-

**Table 4. Dipole moments.**

| $\mu_a$ [D] | 4.51 ± 0.02 | 4.47 ± 0.03 | 4.51 ± 0.02 |
| $\mu_b$ [D] | 0.901 ± 0.005 | 0.736 ± 0.008 | 0.86 ± 0.04 |

![Fig. 3. Transformation matrix.](image-url)
Fig. 4. Transformed matrix of Figure 2.

\[
\begin{align*}
&\begin{array}{cccc}
& \begin{array}{c}
M_J, M_I \\
- J, - I \\
- J, - I \\
J, I \\
J, I \\
\end{array} \\
& \begin{array}{c}
E_{st, |M_J|=J+c} \\
\ + a + x \\
\ + b \\
\ + a - x \\
\end{array} \\
& \begin{array}{c}
|M_J| = J + c \\
0 \\
0 \\
0 \\
\end{array} \\
\end{array}
\end{align*}
\]

The eigenvalues \( E_{st, |M_J|=1} + a \pm x \) correspond to the mixed eigenfunctions

\[
\pm \begin{pmatrix}
|J, \tau, M_J = -1, I, M_I = 1 \\
|J, \tau, M_J = 1, I, M_I = -1 \\
\end{pmatrix}.
\]

It should be mentioned that each rotational level \( J, \tau, I \) is split into \( (J+2)(2I+1) \) sublevels, which may be compared to the number of \( (J+1) \) sublevels in the case without quadrupole effects.

From the result of a second order perturbation calculation applied to the matrix of Fig. 4 a better understanding of the partly complicated pattern of the Stark effect satellites is possible. One has to observe only that second order perturbation calculation is sufficient.

For 2-Cyanofurane two independent fits for \( \mu_a \) and \( \mu_b \) were made. The \( |M_J|=0 \) satellite of the transition \( 4_{23} - 5_{24} \) at 18429.085 MHz has only less than 1\% \( \mu_a \)-contribution. For this reason it was possible to use an estimated \( \mu_a \)-value of 4.5 Debye for the calculation of \( \mu_b \) using the mentioned satellite. After having fixed the \( \mu_b \)-value we determined \( \mu_a \) from Stark satellites with \( |M_J|=0,1,2 \) of the transition \( 3_{13} - 4_{14} \) at 14007.98 MHz (see Table 4).

Prof. Dr. D. Sutter is thanked for his help in the theoretical part of the work. We gratefully acknowledge the support of Deutsche Forschungsgemeinschaft and Fonds der Chemischen Industrie. The calculations were performed at the Rechenzentrum der Universität Kiel.
