For \([\text{Cr(NCS)}_6]^-\) in normal alcohols at 77 K the lifetimes of phosphorescence from the excited doublet state are reported. The lifetimes decrease in the order ethanol > methanol > n-propanol > n-butanol > n-pentanol > n-hexanol > n-heptanol, and the rate constant increases exponentially when the \(0' - 0\) band energy of the \(4E_g \rightarrow 4A_{2g}\) transition decreases.

Introduction

Though extensive studies of the solvent effect on the phosphorescence quenching in Cr III complexes have been carried out [1], our knowledge of the interactions leading to the radiationless relaxation is still insufficient.

In this paper we present the results of lifetime measurements of the phosphorescence of \([\text{Cr(NCS)}_6]^-\) in frozen alcohol solvents. These results are correlated with measurements of the \(0' - 0\) phosphorescence transition. An interpretation of the data based on the classical energy gap law [2] is given.

Experimental

Materials

\((\text{NH}_4)_2[\text{Cr(NCS)}_6]\) was prepared as described in [3]. The commercially available (POCH Gliwice) alcohols were further purified following the literature procedures: methanol and n-propanol — refluxed over Mg + I_2 and distilled, ethanol — distilled after addition of Na, n-butanol, n-pentanol, n-hexanol and n-heptanol — addition of anhydrous K_2CO_3 and distilled.

Apparatus

Absorption spectra were recorded on a Cary 14 spectrophotometer. Phosphorescence spectra were measured on the spectrofluorometer constructed in our laboratory [4]. The phosphorescence beam was passed through a RG 2 glass filter, chopped and focused onto the entrance slit of a GDM 1000 monochromator (Carl Zeiss, Jena). The samples were frozen in a cylindrical cell in a Dewar-flask with liquid nitrogen. A mercury HBO 200 lamp with CuSO_4 solution and BG 18 glass filters was used as an excitation source. Luminescence decay times were measured at 77 K on a TRW Decay Time Fluorometer. A dye laser excited by a N_2 laser was used as an excitation source. Signals were observed on a 556 dual beam Tektronix oscilloscope.

Results

The peak wavelengths of absorption and phosphorescence spectra are given in Table 1. It is observed that the absorption and phosphorescence spectra shift to the red with increasing number of carbon atoms in the aliphatic chain of the alcohol. The total red shift of the absorption peak from ethanol and heptanol is about 410 cm\(^{-1}\) for \(4A_{2g} \rightarrow 4T_{2g}\) absorption and about 180 cm\(^{-1}\) for the phosphorescence \(4E_g \rightarrow 4A_{2g}\) \(0' - 0\) transition. The \(0' - 0\) transition was supposed to be identical with the maximum peak basing on the earlier analysis of phosphorescence spectra of \(K_2[\text{Cr(NCS)}_6]\) carried out by Flint [5]. The phosphorescence lifetimes at liquid nitrogen temperature are listed in Table 1. It is seen that the lifetime decreases in the order ethanol > methanol > n-propanol > n-butanol > n-pentanol > n-hexanol > n-heptanol.

Discussion

It is easily seen from the absorption spectra that the oscillator strenghts of the allowed transition

$^{4}A_{2g} \rightarrow ^{4}T_{2g}$ are not influenced noticeably by the solvent. It may be simply exemplified by comparing the absorption bands of $[\text{Cr(NCS)}_6]^{-3}$ for the two alcohols exhibiting the largest lifetime differences, i.e. ethanol and hexanol (see Figure 1). The oscillator strengths for ethanol and heptanol are practically the same, $f = 2.04 \cdot 10^3$. This means that the decrease of the phosphorescence lifetime should be attributed to the enhancement of the nonradiative decay path of the excited doublet state.

The interaction between the $[\text{Cr(NCS)}_6]^{-3}$ complex ion and alcohols is weak as can be seen from the phosphorescence spectra being not strongly modified by the alcohol solvents [6]. Only the peak positions of the $O' - O$ transition and the vibronic band shift gradually to the red. This leads naturally to a modification of the Franck-Condon factors. Assuming that the microscopic parameters, except the energy distance $\Delta E$ of the $O' - O$ transition, appearing in the Franck-Condon factor remain unperturbed by the solvents we may try to correlate the lifetime variation to the energy distance shift. In Fig. 2 we have plotted the dependence of the decay rates on the energy gap $\Delta E$. A good linearity in the logarithmic scale is observed, which suggests a relation $\tau = A \exp(\alpha \Delta E)$, where $\alpha$ and $A$ are independent of $\Delta E$. This relation may be well rationalized within the framework of the theory of radiationless transitions in the weak coupling limit [2], which predicts the exponential dependence of the rate constant on the energy gap. One question remains to answer: Why does methanol exhibit an unusual behaviour?

In our opinion the exceptional behaviour of $[\text{Cr(NCS)}_6]^{-3}$ in methanol may be attributed to hydrogen bonding. The hydrogen bond strength in methanol is stronger than in other alcohols for which it remains practically constant [7]. This interpretation is consistent with recent results of Cramer and Spears [8], who have reported a strong correlation between hydrogen bonding and nonradiative transitions in solute molecules.

This work has been done under the Program MRL 9.
