O-Methyltransferase, Enzyme, \textit{meta} and \textit{para} Methylation, Phenols, Tobacco Cell Suspension Culture, \textit{Nicotiana tabacum}

The O-methyltransferase of tobacco cell culture was resolved to its \textit{meta} and \textit{para} directing forms by chromatography on DEAE-cellulose. Despite similarities in molecular weights and pH values of the two forms, however, evidence from pH optima, SH-group inhibitors, methylation ratios, SDS-acrylamide gels and mixed substrate experiments indicates the existence of two discrete enzymes acting at the \textit{meta} and \textit{para} positions of caffeic acid and quercetin, respectively; though the latter enzyme was less substrate specific than its \textit{meta} counterpart.

Introduction

O-Methyltransferase (OMT) has been detected in several plant species involving the biosynthesis of phenylpropanoid [1 — 11] and flavonoid [9, 12 — 14] compounds. In the presence of S-adenosyl-L-methionine, OMT transfers the methyl group predominantly at the \textit{meta} hydroxyls of catecholic substrates [15, 16], though the methylation of \textit{p}-hydroxy compounds has also been reported [14, 17, 18]. Recently, several workers have observed OMT activity at both \textit{meta} and \textit{para} hydroxyls of \textit{o}-dihydroxy phenolic compounds [19 — 22]; though it is not known whether one or more enzymes catalyze such methylation. We report here, for the first time, on the isolation and some properties of two forms of OMT from tobacco cell culture. One form mediated the O-methylation of caffeic acid almost predominantly at the \textit{meta} position, and the other, quercetin at the \textit{para} position, but not to the exclusion of other substrates.

Experimental

Culture conditions

Tobacco cell culture (\textit{Nicotiana tabacum} cv. Wisconsin 38) was initiated and maintained on a salt-nutrient medium [23] containing 3% sucrose, 2 $\mu$M indoleacetic acid and 0.1 $\mu$M kinetin. Batch cultures were agitated on a gyrotary shaker (150 rpm) in diffuse light at 24°C and were subcultured at weekly intervals using 10% inoculum.

Enzyme purification

All procedures were carried at 2 — 4°C and buffers were made of potassium phosphate, pH 7.5 containing 5 mM EDTA in the following concentrations: (I) 0.1 M, (II) 5 mM, (III) linear gradient between 10 —  200 mM. Filtered cells were homogenized with Polyclar-AT and 2 volumes buffer I, then centrifuged for 20 min at 20,000 g. The supernatant was stirred for 20 min with Dowex 1 $\times$ 2 and filtered. The filtrate was fractionated with solid ammonium sulphate and the protein which precipitated between 50 — 60% saturation was collected by centrifugation, dissolved in the minimum amount of buffer II then desalted on a Sephadex G-25 column. It was chromatographed successively on DEAE-sepharose, sephacryl S-200 and hydroxyapatite columns and the protein was eluted with a linear gradient (10 — 200 mM) of NaCl in buffer II, buffer II and buffer III, respectively. OMT activity of the different fractions was assayed against caffeic acid, esculetin, daphnetin and quercetin as substrates (Fig. 1) and the purity of active fractions was monitored by acrylamide gel electrophoresis. Sepation of \textit{m}- and \textit{p}-directing activities was achieved by chromatography of the Sephadex G-25 fraction on DEAE-cellulose column and elution with a linear gradient (10 — 150 mM) NaCl in buffer II. The fractions collected were assayed against caffeic acid and quercetin as substrates.
Fig. 1. Structural formulae for substrates and products used with O-methyltransferase assays.

**O-Methyltransferase assay**

The standard assay mixture consisted of 50 nmol substrate (in 10μl DMSO), 7 nmol S-adenosyl-L-[14CH₃]methionine (0.02 μCi), 1.4 μmol β-mercaptoethanol and 10—100 μg protein in a total volume of 250 μl. The mixture was incubated at 35°C for 30 min and the reaction was terminated by the addition of 20 μl of 6 N HCl. Assays were performed in duplicates and the methylated products were extracted twice with diethyl ether (for phenylpropanoids) or ethyl acetate (for quercetin). The products of one assay were counted for total radioactivity in a toluene-based scintillation fluid.

**Identity of reaction products**

The products of the other assay were separated by TLC using different supports and solvent systems (Table 1) followed by autoradiography. The identity of m- and p-methylation products was confirmed by cochromatography with reference compounds and visualization in UV-light (366 nm). Individual compounds were scraped off the TLC plates, mixed with Cab-O-Sil and counted by liquid scintillation.

**Other determinations**

The molecular weights of the two forms of OMT were determined by gel filtration on a calibrated Sephadex G-100 column [25] and by thin-layer gel filtration on Sephadex G-150 [26] using standard proteins. Isoelectric focusing was performed in 10-cm long acrylamide gel columns containing carrier ampholite, pH 3—10 [27].

**Results and Discussion**

Table 1 shows the *meta* and *para* methylation products of the purified enzyme preparation (hydroxyapatite fraction) when assayed against four substrates. Daphnetin was methylated exclusively at the *meta* position, possibly due to its highly nucleophilic 8-OH group. The ratios of *m*/*p*-methylation of the other substrates, however, seem to indicate the presence of two forms of OMT as has been suggested with the citrus cell-free extracts [28]. One form methylated caffeic acid almost predominantly at the *meta* position and the other form methylated quercetin to a large extent at the *para* position.

Whereas the procedure used for enzyme purification did not separate the two forms of OMT activity, examination of the acrylamide gel protein patterns

Fig. 2 shows parallel disappearance of protein band 1 and the appearance of two other proteins (bands 2 & 3, gels a–d). These bands were active against all substrates and the latter two bands were considered to represent the dissociated form of the enzyme. A partial, but fair separation of the two forms of OMT activity was achieved by chromatography on DEAE-cellulose (Fig. 3), and their characteristic properties listed in Table II. Despite the similarities observed in their molecular weights and pI values of the two forms of OMT, there are several properties indicative of the existence of two distinct enzymes acting at the meta and para positions: (a) The elution profile from DEAE-cellulose was

resolved into \textit{m}-directing (\textit{m}/\textit{p}-ratio 11.1) and \textit{p}-
directing (\textit{p}/\textit{m}-ratio 14.8) peaks against caffeic acid
and quercetin respectively; though the latter was
less substrate specific than its \textit{meta} counterpart to the
extent of being able to catalyze significant
methylation of esculetin and caffeic acid. (b) There
were significant differences between the two forms of
the enzyme in their pH optima and their behaviour
shions towards SH-group inhibitors (Table II). The
\textit{meta} directing OMT was more sensitive to \textit{p}-chloro-
mercuribenzoate inhibition than its \textit{para} counterpart, while
the reverse was observed with iodo-
acetate. (c) SDS-acrylamide gel electrophoresis of
bands 2&3 (not shown) seemed to indicate that the
latter are not charge isomers or isoenzymes, but
two distinct proteins with electrophoretic mobilities
coresponding to 70—75 K range and appear to be
intermediate among those reported for other OMT's
[5, 10, 12, 14], (d) More conclusive evidence for the
existence of two discrete enzymes was obtained
from mixed substrate experiments using purified
OMT preparation (hydroxyapatite fraction). The
results shown in Table III indicate that the additive
effect observed when quercetin was added to caffeic
acid is in sharp contrast with the decreased activity
obtained after the addition of either esculetin or
daphnetin. This result is in agreement with kinetic
tory [29] which demonstrates that at near saturating
substrate concentrations, a higher activity is
observable in the presence of two substrates than
with either one alone, if the system contains sepa-
rate enzymes mediating the reactions of both sub-
strates.

To our knowledge, this is the first reported instance
where the \textit{meta} and \textit{para} directing OMT's have been isolated and partially characterized. This
finding together with the report on the presence in
\textit{Ruta graveolens} cell culture of two distinct enzymes
catalyzing the O-methylation of linear furanocou-
marins at the \textit{ortho} and \textit{meta} positions [10] add to
our knowledge of O-methylation at the different positions of phenolic rings.
